

Understanding Deep Learning Errata

December 17, 2023

Much gratitude to everyone who has pointed out mistakes. If you find a problem not listed here, please contact me via [github](#) or by mailing me at udlbookmail@gmail.com.

First printing (Dec. 2023)

1.1 Errors

These are things that might genuinely confuse you.

- Equation 15.9. First integrand should be with respect to \mathbf{x}^* . Correct version is:

$$\begin{aligned} D_{JS} [Pr(\mathbf{x}^*) || Pr(\mathbf{x})] &= \frac{1}{2} D_{KL} \left[Pr(\mathbf{x}^*) \left\| \frac{Pr(\mathbf{x}^*) + Pr(\mathbf{x})}{2} \right\| \right] + \frac{1}{2} D_{KL} \left[Pr(\mathbf{x}) \left\| \frac{Pr(\mathbf{x}^*) + Pr(\mathbf{x})}{2} \right\| \right] \\ &= \frac{1}{2} \int \underbrace{Pr(\mathbf{x}^*) \log \left[\frac{2Pr(\mathbf{x}^*)}{Pr(\mathbf{x}^*) + Pr(\mathbf{x})} \right]}_{\text{quality}} d\mathbf{x}^* + \frac{1}{2} \int \underbrace{Pr(\mathbf{x}) \log \left[\frac{2Pr(\mathbf{x})}{Pr(\mathbf{x}^*) + Pr(\mathbf{x})} \right]}_{\text{coverage}} d\mathbf{x}. \end{aligned}$$

- Section 15.2.4 Consider distributions $Pr(x = i)$ and $q(x = j)$ defined over K bins. Assume there is a cost C_{ij} associated with moving one unit of mass from bin i in the first distribution to bin j in the second;
- Equation 15.14. Missing bracket and we don't need to use \mathbf{x}^* notation here. Correct version is:

$$D_w [Pr(\mathbf{x}), q(\mathbf{x})] = \min_{\pi[\bullet, \bullet]} \left[\iint \pi(\mathbf{x}_1, \mathbf{x}_2) \cdot \|\mathbf{x}_1 - \mathbf{x}_2\| d\mathbf{x}_1 d\mathbf{x}_2 \right].$$

- Equation 15.15. Don't need to use \mathbf{x}^* notation here, and second term on right hand side should have $q[\mathbf{x}]$ term not $Pr(\mathbf{x})$. Correct version is:

$$D_w [Pr(\mathbf{x}), q(\mathbf{x})] = \max_{f[\mathbf{x}]} \left[\int Pr(\mathbf{x}) f[\mathbf{x}] d\mathbf{x} - \int q(\mathbf{x}) f[\mathbf{x}] d\mathbf{x} \right].$$

- Equation 16.12 has a mistake in the second term. It should be:

$$f[h_d, \phi] = \left(\sum_{k=1}^{b-1} \phi_k \right) + (hK - b)\phi_b.$$

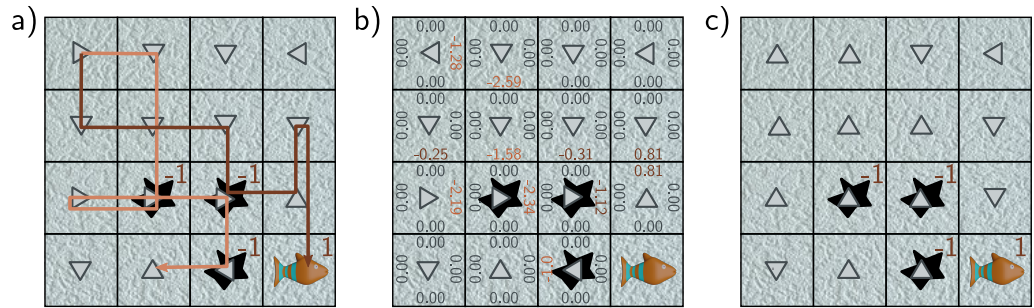

Figure 1.1 Corrected version of figure 12.8

- Equation 17.34.

$$\begin{aligned} \frac{\partial}{\partial \phi} \mathbb{E}_{Pr(x|\phi)} [f[x]] &= \mathbb{E}_{Pr(x|\phi)} \left[f[x] \frac{\partial}{\partial \phi} \log [Pr(x|\phi)] \right] \\ &\approx \frac{1}{I} \sum_{i=1}^I f[x_i] \frac{\partial}{\partial \phi} \log [Pr(x_i|\phi)]. \end{aligned}$$

- Figure 19.11 is wrong in that only the state-action values corresponding to the current state-action pair should be moderated. Correct version above.
- Appendix B.3.6. Consider a matrix $\mathbf{A} \in \mathbb{R}^{D_1 \times D_2}$. If the number of columns D_2 of the matrix is fewer than the number of rows D_1 (i.e., the matrix is “portrait”),
- Equation B.4. Square root sign should cover x . Correct version is:

$$x! \approx \sqrt{2\pi x} \left(\frac{x}{e} \right)^x.$$

- Equation C.20. Erroneous minus sign on covariance matrix. Correct version is:

$$\mathbf{x} = \boldsymbol{\mu} + \boldsymbol{\Sigma}^{1/2} \mathbf{z}.$$

1.1.1 Minor fixes

These are things that are wrong and need to be fixed, but that will probably not affect your understanding (e.g., math symbols that are in bold but should not be).

- Figure 2.3 legend: Each combination of parameters $\phi = [\phi_0, \phi_1]^T$.
- Section 2.3: **1D** linear regression has the obvious drawback
- Figure 3.5 legend: The universal approximation theorem proves that, with enough hidden units, there exists a shallow neural network that can describe any given continuous function defined on a compact subset of \mathbb{R}^{D_i} to arbitrary precision.
- Notes page 38 Most of these are attempts to avoid the dying **ReLU** problem while limiting the gradient for negative values.
- Figure 4.1 legend: The first network maps inputs $x \in [-1, 1]$ to outputs $y \in [-1, 1]$ using a function **comprising** three linear regions
- Equation 4.13 is missing a prime sign:

$$\begin{aligned}\mathbf{h} &= \mathbf{a}[\boldsymbol{\theta}_0 + \boldsymbol{\theta}x] \\ \mathbf{h}' &= \mathbf{a}[\boldsymbol{\psi}_0 + \boldsymbol{\Psi}\mathbf{h}] \\ y' &= \phi'_0 + \phi'\mathbf{h}',\end{aligned}$$

- Equation 4.14: ϕ'_0 should not be bold.

$$y = \phi'_0 + \phi'\mathbf{h}'$$

- Equation 4.17 is not technically wrong, but the product is unnecessary and it's unclear if the last term should be included in it (no). Better written as:

$$N_r = \left(\frac{D}{D_i} + 1\right)^{D_i(K-1)} \cdot \sum_{j=0}^{D_i} \binom{D}{j}.$$

- Equation 5.10. Second line is disambiguated by adding brackets:

$$\begin{aligned}\hat{\phi} &= \underset{\phi}{\operatorname{argmin}} \left[-\sum_{i=1}^I \log \left[\frac{1}{\sqrt{2\pi\sigma^2}} \exp \left[-\frac{(y_i - f[\mathbf{x}_i, \phi])^2}{2\sigma^2} \right] \right] \right] \\ &= \underset{\phi}{\operatorname{argmin}} \left[-\sum_{i=1}^I \left(\log \left[\frac{1}{\sqrt{2\pi\sigma^2}} \right] - \frac{(y_i - f[\mathbf{x}_i, \phi])^2}{2\sigma^2} \right) \right] \\ &= \underset{\phi}{\operatorname{argmin}} \left[-\sum_{i=1}^I -\frac{(y_i - f[\mathbf{x}_i, \phi])^2}{2\sigma^2} \right] \\ &= \underset{\phi}{\operatorname{argmin}} \left[\sum_{i=1}^I (y_i - f[\mathbf{x}_i, \phi])^2 \right],\end{aligned}$$

- Equation 5.15. Disambiguated by adding brackets:

$$\hat{\phi} = \operatorname{argmin}_{\phi} \left[- \sum_{i=1}^I \left(\log \left[\frac{1}{\sqrt{2\pi f_2[\mathbf{x}_i, \phi]^2}} \right] - \frac{(y_i - f_1[\mathbf{x}_i, \phi])^2}{2f_2[\mathbf{x}_i, \phi]^2} \right) \right].$$

- Section 5.6 Removed i index from this paragraph for consistency. Independence implies that we treat the probability $Pr(\mathbf{y}|\mathbf{f}[\mathbf{x}, \phi])$ as a product of univariate terms for each element $y_d \in \mathbf{y}$:

$$Pr(\mathbf{y}|\mathbf{f}[\mathbf{x}, \phi]) = \prod_d Pr(y_d|\mathbf{f}_d[\mathbf{x}, \phi]),$$

where $\mathbf{f}_d[\mathbf{x}, \phi]$ is the d^{th} set of network outputs, which describe the parameters of the distribution over y_d . For example, to predict multiple continuous variables $y_d \in \mathbb{R}$, we use a normal distribution for each y_d , and the network outputs $\mathbf{f}_d[\mathbf{x}, \phi]$ predict the means of these distributions. To predict multiple discrete variables $y_d \in \{1, 2, \dots, K\}$, we use a categorical distribution for each y_d . Here, each set of network outputs $\mathbf{f}_d[\mathbf{x}, \phi]$ predicts the K values that contribute to the categorical distribution for y_d .

- Problem 5.8. Construct a loss function for making multivariate predictions $\mathbf{y} \in \mathbb{R}^{D_i}$ based on independent normal distributions...
- Notes page 94. However, this is strange since SGD is a special case of Adam (when $\beta = \gamma = 0$)
- Section 7.4. Similarly, the derivative for the weights matrix Ω_k , is given by
- Section 8.4.1 When the number of parameters is very close to the number of training data examples (figure 8.11b)
- Figure 9.11 legend: a-c) Two sets of parameters (cyan and gray curves) sampled from the posterior
- Section 10.2.3 The number of zeros we intersperse between the weights determines the dilation rate.
- Section 10.2.4 With kernel size three, stride one, and dilation rate one.
- Figure 10.3. The dilation rates are wrong by one, so should be 1,1,1, and 2 in panels a,b,c,d, respectively.
- Problem 10.2 Equation 10.3 defines 1D convolution with a kernel size of three, stride of one, and dilation one.
- Problem 10.3 Write out the equation for the 1D dilated convolution with a kernel size of three and a dilation rate of two.

- Problem 10.4 Write out the equation for a 1D convolution with kernel size of seven, a dilation rate of **three**, and a stride of three.
- Problem 10.9 A network consists of three 1D convolutional layers. At each layer, a zero-padded convolution with kernel size three, stride one, and dilation **one** is applied.
- Problem 10.10 A network consists of three 1D convolutional layers. At each layer, a zero-padded convolution with kernel size seven, stride one, and dilation **one** is applied.
- Problem 10.11 Consider a convolutional network with 1D input \mathbf{x} . The first hidden layer \mathbf{H}_1 is computed using a convolution with kernel size five, stride two, and a dilation rate of **one**. The second hidden layer \mathbf{H}_2 is computed using a convolution with kernel size three, stride one, and a dilation rate of **one**. The third hidden layer \mathbf{H}_3 is computed using a convolution with kernel size five, stride one, and a dilation rate of **two**. What are the receptive field sizes at each hidden layer?
- Legend to figure 11.15. Computational graph for batch normalization (see problem 11.5).
- Section 12.2.2: Not a mistake, but this is clearer: where $\beta_v \in \mathbb{R}^D$ and $\Omega_v \in \mathbb{R}^{D \times D}$ represent biases and weights, respectively.
- Figure 12.8 has some minor mistakes in the calculation. The corrected version is shown at the end of this document.
- Equation 15.6. Minor problems with brackets in this equation. Should be:

$$\begin{aligned}
 L[\phi] &= \frac{1}{J} \sum_{j=1}^J \left(\log \left[1 - \text{sig}[f[\mathbf{x}_j^*, \phi]] \right] \right) + \frac{1}{I} \sum_{i=1}^I \left(\log \left[\text{sig}[f[\mathbf{x}_i, \phi]] \right] \right) \\
 &\approx \mathbb{E}_{\mathbf{x}^*} \left[\log \left[1 - \text{sig}[f[\mathbf{x}^*, \phi]] \right] \right] + \mathbb{E}_{\mathbf{x}} \left[\log \left[\text{sig}[f[\mathbf{x}, \phi]] \right] \right] \\
 &= \int Pr(\mathbf{x}^*) \log \left[1 - \text{sig}[f[\mathbf{x}^*, \phi]] \right] d\mathbf{x}^* + \int Pr(\mathbf{x}) \log \left[\text{sig}[f[\mathbf{x}, \phi]] \right] d\mathbf{x}.
 \end{aligned}$$

- Equation 16.2 (last line). For some reason, this didn't print properly, although it looks fine in my original pdf. Should be:

$$\begin{aligned}
 \hat{\phi} &= \underset{\phi}{\text{argmax}} \left[\prod_{i=1}^I Pr(x_i | \phi) \right] \\
 &= \underset{\phi}{\text{argmin}} \left[\sum_{i=1}^I -\log \left[Pr(x_i | \phi) \right] \right] \\
 &= \underset{\phi}{\text{argmin}} \left[\sum_{i=1}^I \log \left[\left| \frac{\partial f[z_i, \phi]}{\partial z_i} \right| \right] - \log [Pr(z_i)] \right],
 \end{aligned}$$

- Equation 16.25. ϕ should change to $\hat{\phi}$ on left hand side. Correct version is:

$$\hat{\phi} = \operatorname{argmin}_{\phi} \left[\text{KL} \left[\sum_{i=1}^I \delta[\mathbf{x} - \mathbf{f}[\mathbf{z}_i, \phi]] \middle| \middle| q(\mathbf{x}) \right] \right].$$

- Equation 16.26. ϕ should change to $\hat{\phi}$ on left hand side. Correct version is:

$$\hat{\phi} = \operatorname{argmin}_{\phi} \left[\text{KL} \left[\frac{1}{I} \sum_{i=1}^I \delta[\mathbf{x} - \mathbf{x}_i] \middle| \middle| Pr(\mathbf{x}_i, \phi) \right] \right].$$

- Equation 18.24 has a minor formatting mistake. Better written as:

$$\begin{aligned} & \log \left[\frac{Pr(\mathbf{x}, \mathbf{z}_{1...T} | \phi_{1...T})}{q(\mathbf{z}_{1...T} | \mathbf{x})} \right] \\ &= \log \left[\frac{Pr(\mathbf{x} | \mathbf{z}_1, \phi_1)}{q(\mathbf{z}_1 | \mathbf{x})} \right] + \log \left[\frac{\prod_{t=2}^T Pr(\mathbf{z}_{t-1} | \mathbf{z}_t, \phi_t) \cdot q(\mathbf{z}_{t-1} | \mathbf{x})}{\prod_{t=2}^T q(\mathbf{z}_{t-1} | \mathbf{z}_t, \mathbf{x}) \cdot q(\mathbf{z}_t | \mathbf{x})} \right] + \log [Pr(\mathbf{z}_T)] \\ &= \log [Pr(\mathbf{x} | \mathbf{z}_1, \phi_1)] + \log \left[\frac{\prod_{t=2}^T Pr(\mathbf{z}_{t-1} | \mathbf{z}_t, \phi_t)}{\prod_{t=2}^T q(\mathbf{z}_{t-1} | \mathbf{z}_t, \mathbf{x})} \right] + \log \left[\frac{Pr(\mathbf{z}_T)}{q(\mathbf{z}_T | \mathbf{x})} \right] \\ &\approx \log [Pr(\mathbf{x} | \mathbf{z}_1, \phi_1)] + \sum_{t=2}^T \log \left[\frac{Pr(\mathbf{z}_{t-1} | \mathbf{z}_t, \phi_t)}{q(\mathbf{z}_{t-1} | \mathbf{z}_t, \mathbf{x})} \right], \end{aligned}$$

- Section 20.5.1 In general, the smaller the model, the **larger** the proportion of weights **that** can...
- Section 20.22 Another possible explanation for the ease with which models are trained is that **some** regularization methods **like L2 regularization (weight decay)** make the loss surface flatter and more convex.
- Appendix A. The notation $\{0, 1, 2, \dots\}$ denotes the set of **non-negative** integers.
- Appendix C.5.4 Accent in wrong place: The Fréchet and Wasserstein distances...
